

CDA Position on **Use of Latex in Dentistry**

Latex is most commonly used in dentistry in latex gloves and dental dams.

1. Dental patients should be asked if they have allergies. If they do, they should be asked if they have ever had a reaction to a balloon or rubber gloves as a reaction to these common items may indicate latex allergies.
2. Use non-latex products on patients who say they have reacted to rubber or latex products. Special attention should be given to patients at increased risk due to chronic latex exposure, for example, from repeated catheterization in patients living with spina bifida, paraplegia and quadriplegia. Medical non-latex gloves are available; consult product labeling.
3. Following latex exposure, if a dental worker shows skin problems, the worker should be tested for latex allergy by a medically qualified allergist.
